WIND-TUNNEL INVESTIGATION OF HELICOPTER-ROTOR WAKE EFFECTS ON THREE HELICOPTER FUSELAGE MODELS

John C. Wilson and Raymond E. Mineck
Langley Directorate, U.S. Army Air Mobility R&D Laboratory

SUMMARY

An investigation was conducted in the Langley V/STOL tunnel to study the effects of rotor wake on helicopter fuselage aerodynamic characteristics. A rotor model for generating the wake was mounted close to two of three fuselage models. Force, moment, and pressure data were determined for various combinations of windspeed, sideslip angles, and pitch angles. The data show that the influence of rotor wake on helicopter fuselage yawing moment imposes a significant additional thrust requirement on the tail rotor of single-rotor helicopters for high positive sideslip angles. The influence of the low Reynolds number characteristic of this investigation can make the results conservative if utilized in the specification for design of a tail rotor.

INTRODUCTION

Single-rotor helicopters have experienced degradation of directional control while flying at low speed. (See ref. 1.) The degradation varies with airspeed and yaw angle. It is attributed partially to mutual aerodynamic interference between the tail rotor, main rotor, and vertical tail and partially to the unstable yawing-moment characteristics of the fuselage. An investigation of a tail-rotor interference problem for rearward flight in ground effect is reported in reference 2. The results of the wind-tunnel investigations, reported therein, identified significant adverse effects of the main-rotor wake on the vertical-tail force and on the tail-rotor thrust.

The main-rotor wake has appreciable influence on the fuselage at low airspeeds. Little published information is available to provide an understanding of such effects. What does exist is directed toward the evaluation of conditions in hovering flight only without treatment of conditions at low-flight speeds near hover. Obtaining such information with full-scale flight investigations is difficult because of problems in controlling test conditions and in measuring all relevant parameters.

The purpose of this investigation was to obtain force, moment, and pressure data experimentally for several different fuselage shapes in the presence of a rotor wake. Three fuselage models representative of current helicopter designs were tested in the

Langley V/STOL tunnel at windspeeds of up to 102 knots through $\pm 180^\circ$ sideslip. (When the rotor was mounted, the maximum windspeed was 45 knots.) Forces and moments of the fuselage and the rotor were measured. In addition, pressure distributions were measured for selected test conditions. Comprehensive tables of the pressure data are available in a supplement to this report. A request form for the supplement is found in the back of this report.

SYMBOLS

The longitudinal and lateral data in this report are referred to the body axes (fig. 1). Moment centers are indicated for each of the three models in figure 2. The units used for physical quantities defined in this paper are given in both the U.S. Customary Units and the International System of Units (SI). Measurements and calculations were made in U.S. Customary Units. Factors relating these two systems of units are presented in reference 3. The symbols used are defined as follows; the symbols enclosed in parentheses are used in the data listing of the appendix and supplement.

- A rotor disk area, 0.8107 m^2 (8.728 ft^2)
- b number of rotor blades
- C_A (CAF) axial-force coefficient, $F_A/q_\infty S_p$
- C_H/σ (CHSSIG) in-plane rotor drag coefficient, $H/\rho A V_T^2 \sigma$
- C_l (CRM) rolling-moment coefficient, $M_X/q_\infty S_S l_F$
- C_m (CPM) pitching-moment coefficient, $M_Y/q_\infty S_p l_F$
- C_N (CNF) normal-force coefficient, $F_N/q_\infty S_p$
- C_n (CYM) yawing-moment coefficient, $M_Z/q_\infty S_S l_F$
- $C_{n,s}$ (CYMS) yawing-moment slipstream coefficient, $M_Z/q_s S_S l_F$
- C_p pressure coefficient, $\frac{p - p_\infty}{q_\infty}$
- C_{PR} yaw center of pressure, C_n/C_Y

C_T/σ (CTSSIG)	thrust coefficient, $T/\rho AV_T^2 \sigma$
C_Y (CSF)	side-force coefficient, $F_Y/q_\infty S_s$
$C_{Y,s}$ (CSFS)	side-force slipstream coefficient, $F_Y/q_s S_s$
c	blade chord, 8.9 cm (3.5 in.)
F_A	axial force, N (lbf)
F_N	normal force, N (lbf)
F_Y	side force, N (lbf)
H	rotor and hub drag force normal to thrust, N (lbf)
ℓ	characteristic length (for Reynolds number), m (ft)
ℓ_F	fuselage length, 91.4 cm (36 in.)
M_X	rolling moment, cm-N (in-lbf)
M_Y	pitching moment, cm-N (in-lbf)
M_Z	yawing moment, cm-N (in-lbf)
N_{Re}	Reynolds number, $V\ell/\nu$
p	local pressure, N/m ² (lbf/ft ²)
p_∞	free-stream static pressure, N/m ² (lbf/ft ²)
q_s (QS)	slipstream dynamic pressure, $q_\infty + \frac{T}{A}$, N/m ² (lbf/ft ²)
q_∞ (Q)	free-stream dynamic pressure, $\rho V^2/2$, N/m ² (lbf/ft ²)
R	radius of rotor disk, 50.8 cm (20 in.)
S_p	planform projected area of fuselage, m ² (ft ²)

S_s	side projected area of fuselage, m^2 (ft^2)
T	rotor thrust, shaft axis, N (lbf)
V	free-stream or slipstream windspeed, m/sec (ft/sec)
V_K	free-stream windspeed, knots
V_T (VT)	rotor tip speed, ΩR , m/sec (ft/sec)
x (X)	fuselage station, cm (in.)
α (ALPHA)	angle of attack, deg
β (BETA)	angle of sideslip, deg
ν	air kinematic viscosity, m^2/sec (ft^2/sec)
ρ	air density, kg/m^3 (slugs/ ft^3)
σ	rotor disk solidity, $bc/\pi R$, 0.1114
ϕ	flow angle, deg
χ (CHI)	wake skew angle (from the vertical), deg
Ω	rotor rotational speed, rad/sec

MODEL DESCRIPTION AND INSTALLATION

The three fuselage models used in this investigation (fig. 2) are representative of a current gunship configuration (model 1), a utility configuration (model 2), and a light observation configuration (model 3). The models differed slightly from scaled versions of these configurations in that the tail-boom segments were slightly oversized. The fuselage assemblies were made of molded fiberglass, and each had static-pressure taps located on the model surface to obtain pressure distribution data. The pressure tap locations are given in table I. Each fuselage could be tested with or without a standard vertical tail, although the gunship configuration was tested with a cambered vertical tail and a "V" tail as well. The nomenclature of these configurations is given in table II.

A teetering hub tail rotor from a light observation helicopter simulated the main rotor of each configuration in this investigation. The rotor served to generate the rotor wake that a helicopter fuselage experiences at low-flight speeds. The direction of rotor rotation was conventional, that is, counterclockwise when viewed from above the fuselage. (See fig. 1.) The two blades of the rotor (fig. 3) had a chord of 8.9 cm (3.5 in.), an NACA 0012 airfoil section, and no twist. The rotor diameter was 101.6 cm (40 in.). The blade root cutout was 40.2 percent of the rotor radius. Collective pitch was set by adjustment of pitch links at the rotor hub and measurement of the rotor blade angle. The rotor had no cyclic pitch control and was free to flap. The rotor hub was attached through a five-component strain-gage balance to an air motor which drove the rotor at speeds of 3350 or 3600 rpm. The balance measured the orthogonal rotor shaft forces of thrust, drag, and side force as well as pitching moment and rolling moment. The balance was not capable of measuring yawing moment, that is, torque.

The fuselage models and the rotor were inverted for the tunnel installation as shown in figure 4. The fuselage assembly was mounted on a six-component strain-gage balance attached to a sting. The rotor was mounted through the five-component balance and an air motor to a section of the sting-support structure, the air motor exhaust being ducted through the support structure. The rotor was placed at the appropriate scaled location near the fuselage, although not connected with it. The distance from the rotor flapping axis to the top of the fuselage pylon was 4.9 cm (1.93 in.) for model 1 and 9.4 cm (3.70 in.) for model 2. Model 3 was not tested with the rotor. The whole assembly could be pitched through an angle-of-attack range of $\pm 15^\circ$. The fuselage models were mounted with either the nose upstream or the tail upstream; thus, sideslip angles of $\pm 180^\circ$ were possible. When sideslip angles were greater than $\pm 90^\circ$, the sting was mounted through the nose of the fuselage and a rounded plug was inserted in the tail of the model.

TESTING AND CORRECTIONS

The investigation was conducted in the Langley V/STOL tunnel. The test section has a width of 6.63 m (21.75 ft) and a height of 4.42 m (14.5 ft). The fuselage and rotor were located approximately in the center of the test section. This test program utilized a free-stream windspeed range of 15 to 102 knots (1 knot = 0.5144 m/s). Since errors due to blockage, slipstream contraction, flow misalignment, and tunnel wall effects have been found to be small for models of this size in this tunnel, no corrections for these types of error have been applied to the data. The maximum tunnel wall effect was calculated (ref. 4) to be a flow angle-of-attack change of 1.0° ; this effect occurred at the lowest free-stream velocity and at the lowest downwash angle (which therefore was the most extreme wake angle effected).

Since yawing moment and side force were the components of primary interest in this program, the force and moment measuring balance was chosen with the range most suitable for these components. The maximum forces and moments that the fuselage balance was capable of measuring (the associated accuracy was ± 0.5 percent of the maximum force or moment) are given in the following table:

F_A , N (lbf)	± 66.7	(± 15)
F_Y , N (lbf)	± 222.4	(± 50)
F_N , N (lbf)	± 222.4	(± 50)
M_X , cm-N (in-lbf)	± 226	(± 20)
M_Y , cm-N (in-lbf)	± 1130	(± 100)
M_Z , cm-N (in-lbf)	± 1130	(± 100)

The accuracy of data presented in coefficient form is, of course, inversely proportional to the dynamic pressure and nondimensionalizing areas and lengths, as indicated in "Symbols." The data repeatability was good because of the manner of acquiring data. A data point is normally 10 samples. When pressure data are obtained, the balance measurements are sampled 48 times. Thus, there is a statistical improvement in accuracy of 3.3 when 10 samples are taken and 6.9 when 48 samples are obtained. (See ref. 5.)

The rotor balance measured five components, although only two of these, thrust and drag, were of interest. The thrust range capability was 0 to 623 N (0 to 140 lbf) with an accuracy of ± 2.2 N (± 0.5 lbf). The drag range was ± 133 N (± 30 lbf) with an accuracy of ± 2.7 N (± 0.6 lbf). The statistical improvement in data repeatability, as a result of the data compiling procedure, is true for these data as well.

The accuracy of attitude angles and windspeed also influenced data accuracy. Angle of attack α and angle of sideslip β were within 0.1° of the nominal value. Windspeed measurements were within 0.5 knot. Collective pitch settings were accurate within $\pm 0.1^\circ$. For most of the test program, the rotor collective pitch setting was 8.0° with a rotor speed of 3600 rpm; for early test runs, the pitch setting was 9.0° with a rotor speed of 3350 rpm.

PRESENTATION OF DATA

The results of the wind-tunnel investigation are presented in terms of conventional aerodynamic force, moment, and pressure coefficients. As an aid to the evaluation and analyses of the results, figures 5 and 6 are presented. Figure 5 shows the variation of rotor thrust, rotor drag, and calculated wake angles as a function of windspeed for the rotor used in this test program when tested alone. Figure 6 shows typical main-rotor power for a helicopter as the equivalent yawing-moment coefficient required of a tail rotor for antitorque. Yawing-moment (body axis) and side-force coefficient data are

presented in figures 7 to 48. The appendix has a complete listing of the six components of fuselage forces and moments (in coefficient form) measured as well as the thrust coefficient. Selected portions of the pressure coefficient data are presented in figures 51 to 70. Comprehensive tables of the pressure data are available in a supplement to this report which is available on request. Inclusion of the test run number in figures and data listings provide a means of correlating test conditions and data.

DISCUSSION OF RESULTS

The rotor wake at low-flight speeds immerses a helicopter fuselage in a swirling, relatively strong flow that can be expected to strongly affect fuselage aerodynamics. The flow is complex and self-distorting. (See ref. 6.) Axial swirl is induced by the profile drag of the rotor blade; there are strong vortices generated by the rotor blade tips; the lateral extremities of the wake roll up as does any wake trailed by a finite-span lifting surface. Wake skew angle is an adequate general indicator of the strength of the momentum flux through the rotor relative to the free-stream flow; the angle is determined as a function of rotor thrust and drag according to the derivation in reference 4. High thrust and low windspeed results in a small angle from the vertical. As windspeed increases or thrust decreases, the angle approaches a value of 90° . Figure 5 indicates that this angle varies significantly with windspeed in the range of 0 to 60 knots.

The performance characteristics of the rotor alone are indicated in figures 5(a) and 5(b). Because a fixed collective was used throughout the test program, disk loading increased moderately as the free-stream windspeed was increased. The resulting variation of wake skew angle for the investigation is shown in figure 5(c). The data may be

read for different values of lift if the appropriate values of wake skew angle and then the corresponding airspeed are determined.

Yawing Moment and Side Force

Since yawing-moment characteristics, supplemented by side-force characteristics, were of the greatest interest, only these data are presented in figures 7 to 48. The configurations consisted of combinations of the three fuselage shapes, with and without vertical- and horizontal-tail surfaces, and with and without rotor. Configuration nomenclature used in the figure keys and illustrations of each configuration are given in table II.

Model 1 was tested with four vertical-tail configurations. Figure 7 shows the comparison of yawing moment for the four configurations. It is evident that the fuselage without a vertical tail is moderately unstable in the range of sideslip -20° to 20° (at an angle of attack of 0°). The three tails provide a moderate stabilizing effect in that range. Also, they are nearly identical in yawing-moment characteristics throughout the sideslip range. Figures 8 to 11 show the results of varying windspeed for the four tail configurations. No significant anomalous aerodynamic characteristics attributable to Reynolds number effects are evident. Qualitative consideration of possible Reynolds number effect is presented in the section "Reynolds Number." In general, the data for model 1 configurations without the influence of rotor wake show reasonable, symmetric variations about a sideslip of 0° .

The strong influence of the rotor wake on model 1 is shown in figures 12 to 16. Maximum yawing-moment peaks for rotors-off configurations occur at angles of sideslip of 120° to 130° . With the rotor wake, these peaks occur at sideslip angles as low as 70° . The data show discontinuities at low windspeeds (15 to 25 knots) at sidewind conditions (sideslip angles near $\pm 90^{\circ}$). This characteristic is attributable to the configuration change from nose to tail mounting on the sting. The usual symmetry of yawing-moment data about a sideslip of 0° for rotor off is altered appreciably with the addition of a rotor wake. In general, the rotor wake has a much stronger effect on C_n at lower airspeeds and causes the fuselage to stabilize in yaw about a sideslip angle of approximately 20° .

The directional characteristics of model 2 are similar to those of model 1; that is, the same pattern of yawing-moment variation influence is evident in figures 17 to 21. The maximum moment occurs at 120° to 130° with the rotor off. With the rotor on (figs. 22 to 25), the peak occurs at a sideslip angle as low as 60° . As with data for model 1, data for the model with the rotor wake effect show discontinuities at sideslip angles of 90° and -90° . (See figs. 22(g) and 23(g).)

Model 3 was investigated without the rotor only. A comparison of its directional characteristics with models 1 and 2 is shown in figure 26. In the sideslip range of -20° to 20° , it is slightly less stable than models 1 and 2. Otherwise, the variation of yawing-

moment and side-force characteristics of model 3 with sideslip is very similar to those of models 1 and 2.

To determine how well the rotor-on data could be condensed to a single curve representative of all windspeeds, the yawing-moment and side-force data were nondimensionalized with slipstream dynamic pressure rather than with windstream dynamic pressure. The results are shown in figures 27 to 34. For models 1 and 2 with vertical tails, the data do condense reasonably well, especially for the sideslip range of 20° to 90° . This range is the most significant range in that it is burdening the tail rotor. However, the scatter in the data and variation in trends reflect the complexity of the variation in the total flow field with changes in windspeed (and wake skew angle).

All three models were subjected to angle-of-attack excursions at various sideslip angles. The results are shown in figures 35 to 48. The effect of angle of attack on yawing moment of the various configurations is moderate. This result appears to disagree with the conclusions of reference 7. (The shape of model 2 of this investigation is similar to that of model D of ref. 7.) Reference 7 dealt with helicopter fuselage models which have a rotating hub. However, two aspects explain the disagreement. First, the hub of reference 7 incurred a Magnus effect contributing to side force at zero sideslip. This condition effected sidewash at the vertical tail and contributed yawing moment at zero sideslip. Secondly, reference 7 explored a limited sideslip range of $\pm 8^{\circ}$; whereas, this investigation explored the whole sideslip range of $\pm 180^{\circ}$ but did not acquire data at sideslip between 0° and $+10^{\circ}$ or 0° and -10° . The moderate effect of angle of attack on yawing moment and side force at various sideslip angles makes the results for the sideslip excursions of $\pm 180^{\circ}$ conducted at an angle of attack of 0° generally applicable for moderate angles of attack.

The application of the results of this investigation is useful in the determination of the required yaw control capability of the tail rotor on a single main-rotor helicopter. The results indicate that for the sideslip range of approximately 25° to 170° , the yawing moment due to rotor wake is additive to the basic main-rotor antitorque requirement of a tail rotor. For the rest of the sideslip range, of course, the yawing moment due to rotor wake reduces the yaw control required of the tail rotor. Figure 49 shows the variation with windspeed of this additional requirement for selected sideslip angles; this figure has data for models 1 and 2 and with and without vertical tails.

Figure 50 shows comparisons of the envelopes (maximum and minimum yawing moment for the sideslip range of $\pm 180^{\circ}$) of wake-affected yawing-moment coefficient with a typical envelope (see fig. 6) of equivalent yawing-moment coefficient required of a tail rotor for antitorque. Both forms of yawing-moment coefficients are shown for model 2 with the tail mounted. The slipstream dynamic-pressure coefficient (fig. 50(b)) provides a clearer measure of the relative magnitude of the burden of fuselage yawing moment than

that provided by the yawing-moment coefficient based on windstream dynamic pressure. It is evident that at extreme sideslip and windspeed a tail rotor may be required to provide a total yaw capability of nearly twice the main-rotor antitorque requirement.

Pressure Distribution

Pressures were measured for selected test conditions and configurations. Of these data, the pressure coefficients measured on the sides of the fuselages are presented in figures 51 to 62 to show sideslip effects. The pressure coefficients for the top and bottom center line of the fuselage are presented in figures 63 to 70 to show the effects of angle of attack. These data serve to describe the load distributions and the resultant yawing moment of the fuselages as shown previously in figures 7 to 48.

The influence of rotor wake on pressure distributions on the model 1 fuselage is shown in figures 54 to 56. Without the rotor, coefficients range from -2.0 to 1.0 (figs. 51 to 53). With the rotor, rotor wake effect results in coefficients greater than 1.0 and less than -3.0. This greater range is because the dynamic pressure of the regions of the rotor wake that impinge on the fuselage is greater than the slipstream dynamic pressure. A comparison of figure 51 with figure 54 illustrates this amplification caused by rotor wake. Also evident in figure 54, is the diminishing influence of rotor wake on fuselage pressures as the windspeed increases to 45 knots. The presence of the vertical tail, as expected, affects the pressures only to a minor degree. The data obtained for the portion of the sideslip range near a rearward flight condition are presented in figures 53, 55, and 56. The trends of pressure patterns for model 1 are in agreement with the yawing-moment variations with sideslip and windspeed shown in figures 12, 13, and 14.

Pressure patterns obtained for model 2 at various sideslip angles and windspeeds (figs. 57 to 61) differ from those of model 1. There is, of course, a distinctive difference in fuselage shape of the models which accounts for the pressure difference. Model 2 has a bulbous forward fuselage, fairing into a slender "tail boom," which supports the vertical tail whereas model 1 is relatively slender overall. Neither model had pressure taps close enough to the end of the fuselage to provide for an evaluation of the discontinuity in yawing-moment variation at $\beta = 90^\circ$ and $\beta = -90^\circ$, as mentioned previously.

Some of the pressure patterns obtained for model 3, which was tested without the rotor, are shown in figure 62 for various sideslip angles. The patterns are similar to those of models 1 and 2 (figs. 51 and 57) and apparent differences reasonably reflect the difference in fuselage shape.

The effect of angle of attack on pressure distributions along the center line of the fuselages is moderate as shown in figures 63 to 70. A comparison of figures 65, 66, and 69 (rotor on for models 1 and 2) with figures 63, 64, 67, and 68 indicates that this effect is primarily attributable to the variation of rotor thrust with angle of attack.

The center of pressure for these pressure distributions can be evaluated from the force and moment data; for pitch center of pressure, pitching moment divided by normal force; and for yaw center of pressure, yawing moment divided by side force. Figures 71, 72, and 73 show this for (1) comparisons of the three models, (2) rotor wake effect on model 1, and (3) rotor wake effect on model 2. In an ideal fluid, a slender streamlined fuselage shape can have the center of pressure at infinity where the resulting pressure distribution yields only a pure couple with no resultant force. For real fluids and moderate angles of attack or sideslip, the center of pressure moves usually to a position moderately ahead of the nose of the fuselage. For the models of this investigation, this is essentially true for the sideslip range of $\pm 10^\circ$. For the extreme angles of sideslip, beyond this range, the center of pressure moved behind the moment resolving center, close to the center of the fuselage. (See fig. 71.) The influence of the rotor wake served to make the flow conditions affecting the model pressure distributions even less ideal (figs. 72 and 73) and thus the center-of-pressure variations are very erratic.

Reynolds Number

The significance of Reynolds number that affected the model characteristics is not readily evaluated. Only qualitative considerations are possible for several reasons. First, the wake of a rotor is a complex turbulent flow which impinges on sections of the fuselage. Second, even without the rotor wake, the extreme sideslip angles that these models were subjected to introduces the uncertainty of defining an appropriate characteristic length for Reynolds number. The length could be the total axial dimension of the fuselage as in references 7 and 8. However, the cross-flow velocity component, that is, the velocity perpendicular to the fuselage longitudinal axis, becomes important as the sideslip angle increases. The characteristic length for the cross-flow Reynolds number is typically the depth of the fuselage, as shown in sketch (a), which varies over the length of the fuselage:

ORIGINAL PAGE IS
OF POOR QUALITY

Sketch (a)

Consideration of Reynolds number effects can be based on the difference in characteristics between subcritical and supercritical flow regimes. The Reynolds number that

the models experienced ranged from 5394/cm (13 700/in.) to 23 622/cm (60 000/in.) for windspeeds of 15 to 60 knots and depending on rotor on or off. The turbulence created by the rotor would tend to increase the Reynolds number. In general, the models experienced less than the "critical" Reynolds number, that is, where force coefficients decrease as Reynolds number increases. Full-scale Reynolds number would be in the supercritical range, that is, greater than 400 000.

The significance of Reynolds number effects is shown by references 9 to 13. In these, the variation of aerodynamic forces of various cylindrical shapes is defined. Reference 12 presents extensive data regarding a variety of noncircular two-dimensional cylinders and includes the elliptical shape which is most pertinent to the three fuselage models in this test program. Data from reference 9 (shown in fig. 74) indicate that the yawing moment shown for the fuselages tested without the vertical tails should be reduced by 50 percent to be representative of full-scale values.

The vertical-tail fins mounted on the fuselages provided a significant contribution to the side force and yawing moment. The influence of extremely low Reynolds number on airfoils is dealt with in reference 13. Therein, the Reynolds number influence is indicated to be predominantly near the maximum lift of an airfoil, that is, near or at stall angles of attack. Since for the wide range of sideslip angles in this program, the maximum lift (effectively side force) that the tails experience occurs in only two small regions of sideslip angles (10° to 20° and -10° to -20°), the significance of low Reynolds number for the tail surfaces appears to be minimal.

The other forces and moments (lift, drag, pitching moment, and rolling moment) are also affected by low Reynolds number. Reference 8 describes a wind-tunnel investigation of a full-scale helicopter fuselage similar in shape to model 2 of this investigation. Longitudinal data therein were obtained at a Reynolds number, based on fuselage length, of 42×10^6 . A comparison of these data with data for model 2 obtained at a Reynolds number of 1.8×10^6 is shown in figure 75. The correlation is rather poor and may be explained by the large difference in test Reynolds number. Differences in body shape and minor differences in configuration may contribute to a lesser degree to the poor correlation. Definition or evaluation of the influence of Reynolds number is evidently very uncertain for longitudinal data; however, these components are of less significance regarding the objectives of this investigation.

SUMMARY OF RESULTS

The results of a wind-tunnel investigation of influence of rotor wake on helicopter fuselage models indicate the following conclusions:

1. The rotor wake significantly increases fuselage yawing moment that the tail rotor must counteract for sideslip angles greater than 20° .

2. The influence on the fuselage yawing moment of the low Reynolds number characteristics of this investigation is significant and makes the results of this investigation conservative if utilized for the design specification of a tail rotor.

APPENDIX

FORCE AND MOMENT DATA

The force and moment data, presented graphically in figures 7 to 48, are presented in tabular form in this appendix. Each block of data represents one run or parameter sweep. The configuration numbers are described in table II and the table column headings are described in the "Symbols" section. The angles α and β are in degrees; Q and QS, are in N/m²; velocity is in knots; and tip speed, VT, is in m/sec.

4. Title and Subtitle WIND-TUNNEL INVESTIGATION OF HELICOPTER-ROTOR WAKE EFFECTS ON THREE HELICOPTER FUSELAGE MODELS				5. Report Date March 1975	
				6. Performing Organization Code	
7. Author(s) John C. Wilson and Raymond E. Mineck, Langley Directorate, U.S. Army Air Mobility R&D Laboratory				8. Performing Organization Report No. L-9454	
9. Performing Organization Name and Address NASA Langley Research Center Hampton, Va. 23665				10. Work Unit No. 760-63-02-01	
				11. Contract or Grant No.	
				13. Type of Report and Period Covered Technical Memorandum	
12. Sponsoring Agency Name and Address National Aeronautics and Space Administration Washington, D.C. 20546				14. Sponsoring Agency Code	
15. Supplementary Notes					
16. Abstract The effects of rotor wake on helicopter fuselage aerodynamic characteristics were investigated in the Langley V/STOL tunnel. Force, moment, and pressure data were obtained on three fuselage models at various combinations of windspeed, sideslip angle, and pitch angle. The data show that the influence of rotor wake on the helicopter fuselage yawing moment imposes a significant additional thrust requirement on the tail rotor of a single-rotor helicopter at high sideslip angles. Influence of the low Reynolds number characteristic of this investigation can make the results conservative if utilized in the specification for design of a tail rotor.					
17. Key Words (Suggested by Author(s)) Rotor wake Yawing moment Helicopter			18. Distribution Statement Unclassified - Unlimited Subject Category 02 Aerodynamics
